FETOTOMY IN A MARE

FETOTOMY IN A MARE

Laura Martín Sánchez (Erasmus student)

INTRODUCTION What is it?:

Fetotomy is surgical procedure that when we have a dystocia, in which we seek to reduce the segments that are too large to pass through the calf obstetric canal, as well as removing his limbs in abnormal presentations

DFetotomy part: one part of the body is removed. DFetotomy Total: fetus shatters into pieces.

The embryotomy is a procedure that aims to

 a. Decrease the segments that are too large for the obstetric canal.
 b. Remove limbs in abnormal presentations that can not be accommodated
 c. Remove feat parts to make room for the various types of correction.
 d. In childbirth with fetal malformation INDICATIONS AND CONTRAINDICATIONS

INDICATIONS AND CONTRAINDICATIONS CINDICATIONS: DAbsolute or relatively large (especially dead) fetuses that are not on orced traction. DHard stricture dilation and inadequate soft channel. Uhren the fetal abnormal static and can not be corrected. D When fetal deformations.

C<u>CONTRAINDICATIONS:</u> Dinsufficient dilatation. DThe general condition of the patient is compromised. DRupture soft canal or uterus.

EQUIPMENT EQUIPMENT
1.Universal Embriotom wire saw
2.Detachable Probe enhilar
3.Dual handles wire saw.
4.Wire saw
4.Wire saw
5.Pasalazo
6.Articulated hook.
7.metal closures
8.Slide Iron holder with five grooves for attaching chains extractors.

Equipment for epidural anesthesia.
 2.Obsterric lubricant, for example Vaseline (large quantities needed).
 3.Clean warm water.
 4.Paper towels.
 5.Sedatives.
 6.Uterine relaxant (clenbuterol) may be useful.
 7.Nasogastric tube - it may be necessary to prevent / reduce abdominal effort

WHEN FETOTOMY, AND WHEN CESAREAN? Cesarean CBicornual Pregnancy COversized fetus Cvery small mare (fetotomy impossible) Calteration of the presentation (position and immutable positions) Chydrocephalus (monstrosties) Cirreducible uterine torsion Cpelvic deformation (fractures) Culvovaginal trauma CContractions advanced stage 1 or 2 chronic metritis

Fetotomy ¢An oversized fetus

cAn oversized fetus CAbnormalities in the presentation, position or posture or a combination of these that can not be corrected by mutation. CWhen the fetus is emphysematous and prey is toxic. Ceconomic situation: A fetotomy may allow delivery of the fetus. Cfetotomy recommended if removal can be achieved after 1 or 2 cuts. CThe management of retained placenta should be started immediately after

A. EMBRYOTOMY IN THE PREVIOUS PRESENTATION 1. <u>Amputation of the head and neck</u>. Collar is cut as close to the chest as possible.

Da. The head and neck extended Db . Head in lateral or ventral flexion. Pasalazo saw the sets.

2. Amputation of a former member : Cut between the back and chest.

Da. The extended member Db . The member fully rearward

A. EMBRYOTOMY IN THE PREVIOUS PRESENTATION (2) 3. <u>Cut the body:</u>

Da. Cross section of the thorax behind Db . Partial cross section behind the scapular leaves. After cross section behind the chest.

4. Sagittal section of the pelvis . Saw is placed with pasalazo .

Dsupplemental Sections: Partial amputation of a forelimb . When both forelimbs are placed in the pelvis , it may be necessary to amputate get enough space for the amputation of the head.

Exception and a cardiological sector of the control of the control

B. EMBRYOTOMY IN THE SUBSEQUENT PRESENTATION 1. <u>Amputation of a hind limb.</u>

Da. The extended member Db. The member fully directed forward. Pasalazo saw the sets.

2. Transverse amputation of the lower back

3. Evisceration.

4. <u>Cut the body:</u>
Ba. Amputation of the posterior segment of the thorax.
Bb. Diagonal cut anterior chest (division diagonal length). Pasalazo saw the sets.

ISupplemental Sections: Partial amputation of a hind limb. Cut below the hock. Cross partial amputation of the croup. When the members are positioned along its length under the belly, may decrease the rump by a partial amputation. (Figure 26),
